

3/9

Java provides a special class called “Exception,” which appears when errors occur while the code runs.

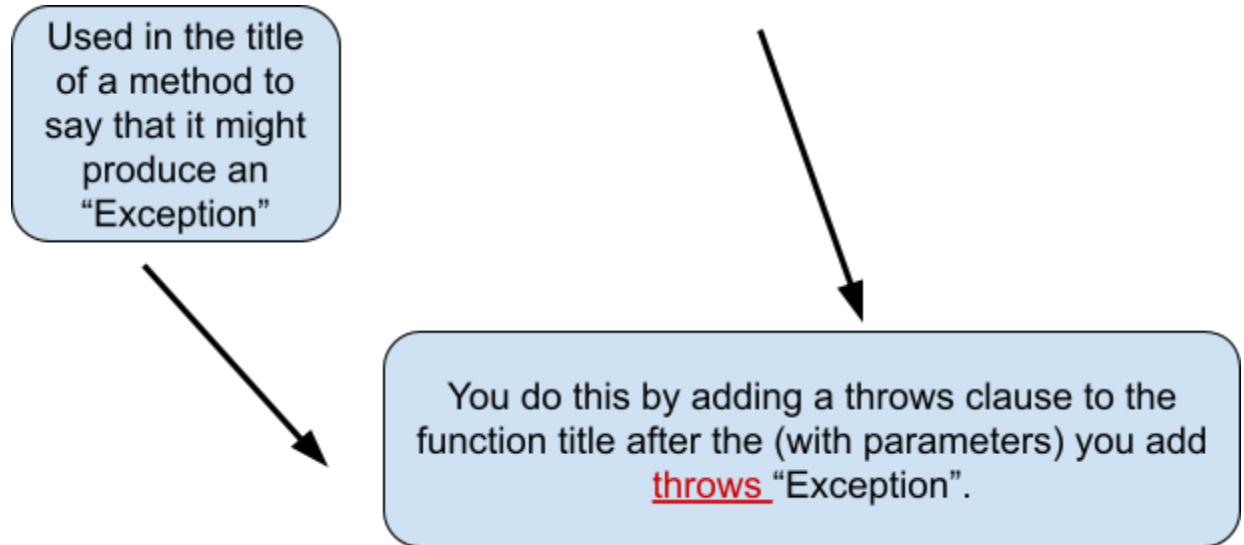

### To create an exception

- Use: `new Exception ("Something failed");`
- To throw it: `throw new Exception ("...");`

- 
- When you throw an exception, it is caught by some code, including the word catch or the method it lies in ends at once.
  - If the method might be ended, it needs to say so in its title line.

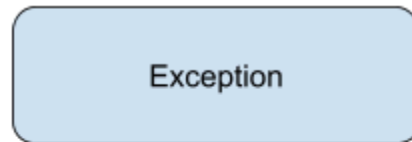

- To catch an exception we place a piece of potentially buggy code into a try {  
Block  
} Catch (Exception e){  
}

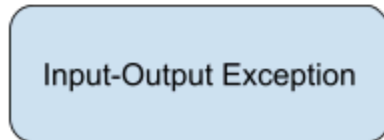

**3 new pieces of Java to deal with Exception objects, it requires 4 words of Java language:**

- Throw: When we discover a problem, we throw a new exception
- Throws: goes into the title of a method that could throw
- Try Catch: used together to catch any exceptions

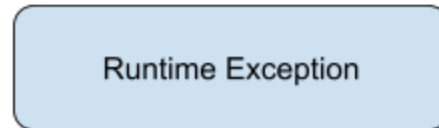

Java uses this if meets an Input-Output problem

Java can't deal with data in its program, typically correspond to program bugs.

Everything else is checked exception

Unchecked exception

These don't need to be caught

- You don't have to say that a method throws a Runtime Exception
